Color doppler and power doppler imaging to help differentiate subpleural consolidations in dogs and cats

The main goal of this lecture is to present various types of vascular patterns within subpleural consolidations found in dogs and cats. Furthermore, we plan to present vascular criteria that help in differentiation of pathologic processes in the lungs and illustrate these criteria by presenting a few case examples from our clinical practice. We will also discuss general principles of applying color doppler modality in lung ultrasound of dogs and cats.
